**Abstract:** Cancer statistics for adolescents and young adults (AYAs) (aged 15-39 years) are often presented in aggregate, masking important heterogeneity. The authors analyzed population-based cancer incidence and mortality for AYAs in the United States by age group (ages 15-19, 20-29, and 30-39 years), sex, and race/ethnicity. In 2020, there will be approximately 89,500 new cancer cases and 9270 cancer deaths in AYAs. Overall cancer incidence increased in all AYA age groups during the most recent decade (2007-2016), largely driven by thyroid cancer, which rose by approximately 3% annually among those aged 20 to 39 years and 4% among those aged 15 to 19 years. Incidence also increased in most age groups for several cancers linked to obesity, including kidney (3% annually across all age groups), uterine corpus (3% in the group aged 20-39 years), and colorectum (0.9%-1.5% in the group aged 20-39 years). Rates declined dramatically for melanoma in the group aged 15 to 29 years (4%-6% annually) but remained stable among those aged 30 to 39 years. Overall cancer mortality declined during 2008 through 2017 by 1% annually across age and sex groups, except for women aged 30 to 39 years, among whom rates were stable because of a flattening of declines in female breast cancer. Rates increased for cancers of the colorectum and uterine corpus in the group aged 30 to 39 years, mirroring incidence trends. Five-year relative survival in AYAs is similar across age groups for all cancers combined (range, 83%-86%) but varies widely for some cancers, such as acute lymphocytic leukemia (74% in the group aged 15-19 years vs 51% in the group aged 30-39 years) and brain tumors (77% vs 66%), reflecting differences in histologic subtype distribution and treatment. Progress in reducing cancer morbidity and mortality among AYAs could be addressed through more equitable access to health care, increasing clinical trial enrollment, expanding research, and greater alertness among clinicians and patients for early symptoms and signs of cancer. Further progress could be accelerated with increased disaggregation by age in research on surveillance, etiology, basic biology, and survivorship. *CA Cancer J Clin* 2020;0:1-17. © 2020 American Cancer Society.

**Keywords:** adolescent cancer, childhood cancer, epidemiology, pediatric cancer

## Introduction

Cancer in adolescents and young adults (AYAs) is defined by the National Cancer Institute as diagnoses occurring among those aged 15 to 39 years<sup>1</sup> and is unique from cancer diagnosed in other age groups because of important differences in the distribution of cancer types, intrinsic and extrinsic risk factors, tumor biology, and prognosis and survivorship. An increasing body of evidence indicates that tumors in AYAs are molecularly distinct from those in both younger and older age groups, possibly suggesting differences in etiology and effective treatment.<sup>2-4</sup> In addition, compared with older patients with cancer, AYAs have a higher risk of long-term and late effects, including infertility, sexual dysfunction, cardiovascular disease, and future cancers,<sup>5-8</sup> whereas compared with childhood cancer survivors, the risk of severe late effects is lower.<sup>9</sup> AYAs are also more likely than older patients with cancer to experience delays in diagnosis for some cancers because of higher uninsured rates, a lack of cost-effective early detection methods, and the rarity of cancer at this age.<sup>10,11</sup>

Despite rapid progress in the scientific understanding of cancer in AYAs, important research gaps in etiology, basic biology, treatment, and survivorship persist, partly because this age group continues to be grouped with children and/or older adults in many epidemiologic studies. Even within AYA studies, data are often presented in aggregate, masking important differences across AYA age groups. This article summarizes population-based trends in cancer incidence, mortality, and survival among AYAs, with a focus on the heterogeneity within this population, and also briefly reviews survivorship issues.

## Materials and Methods

### Data Sources

Population-based cancer incidence data in the United States are collected by the National Cancer Institute's Surveillance, Epidemiology, and End Results (SEER) program and by the Centers for Disease Control and Prevention's National Program of Cancer Registries (NPCR). Historical incidence and survival trends (1975-2016) were based on data from the 9 oldest SEER registries, representing 9% of the US population.<sup>12</sup> Data from the 18 SEER registries, covering 28% of the US population, were the source for 5-year relative and cancer-specific survival rates.<sup>13</sup> Combined SEER and NPCR data for 1995 through 2016, as provided by the North American Association of Central Cancer Registries (NAACCR), were the source for the estimated numbers of new cancer cases in 2020, cross-sectional incidence rates (2012-2016), stage distribution (2012-2016), and 10-year average annual percent changes (AAPCs) in incidence rates (2007-2016).<sup>14,15</sup> Analyses of incidence trends from 1995 through 2016 were based on all available data for the 50 states and the District of Columbia, covering 95% of the US population during that time.

Mortality data covering all 50 states and the District of Columbia were obtained from the National Center for Health Statistics and were the source for death rates in the most recent time period (2012-2016) and long-term trends (1975-2017).<sup>16,17</sup> Incidence and mortality rates for American Indians/Alaska Natives (AI/ANs) were based on cases and deaths in Preferred/Referred Care Delivery Area counties. The 2018 National Health Interview Survey was used for estimates of self-reported cervical cancer screening.<sup>18</sup>

### Statistical Analyses

Case estimates were calculated by applying the age-specific proportions of cases diagnosed during 2015 through 2016 from the NAACCR analytic file to the previously published total number of estimated cases in 2020.<sup>19</sup> Similarly, we calculated the estimated number of cancer deaths among AYAs by applying the proportion of

**TABLE 1. Estimated Cancer Cases and Deaths in Adolescents and Young Adults by Age, 2020**

AGE	ESTIMATED CASES	ESTIMATED DEATHS
15-19 years	5800	540
20-29 years	24,900	2210
30-39 years	58,800	6520
<b>Total</b>	<b>89,500</b>	<b>9270</b>

deaths in that age group during 2016 through 2017 to the previously published estimates for total cancer deaths in 2020. Estimates by cancer type for cases are provided for sexes combined for stability and are not provided for cancer deaths because of sparse data.

Incidence and death rates, expressed per 100,000 population, were calculated using SEER\*Stat (version 8.3.6) software and were age standardized to the 2000 US standard population.<sup>20</sup> In analyses of incidence trends for selected sites using NAACCR data, we applied delay adjustment factors from the US Cancer Statistics data file.<sup>21</sup> All cases were classified according to the AYA site recode/World Health Organization 2008 definitions, based on the *International Classification of Diseases for Oncology*, third edition,<sup>22,23</sup> with the exception of melanoma of the skin and solid tumors other than brain, which were classified according to SEER site recode/World Health Organization 2008 definitions for comparability to statistics in older age groups as well as differentiation between uterine cervix and uterine corpus. Trends for colorectal cancer incidence excluded the appendix (code C18.1). Causes of death were classified according to the *International Statistical Classification of Diseases and Related Health Problems*, 10th revision.<sup>24</sup> It is important to note that, because of differences in classification, incidence and mortality statistics herein are not directly comparable.

The annual percent change in rates was quantified using the National Cancer Institute's Joinpoint Regression Program (version 4.7.0.0).<sup>25</sup> Screening prevalence estimates were calculated using SAS-callable SUDAAN (version 11.0.1; RTI International, Research Triangle Park, North Carolina) and accounted for the complex survey design.

## Selected Findings

### Expected Cases and Deaths in 2020

In 2020, there will be approximately 89,500 new cancer cases and 9270 cancer deaths in AYAs aged 15 to 39 years in the United States (Table 1). The distribution of cancers among AYAs varies substantially by age (Fig. 1). In particular, adolescents (defined hereafter as individuals aged 15-19 years) have a unique cancer profile that includes a higher proportion of childhood cancers (eg, Hodgkin lymphoma, acute lymphocytic leukemia [ALL]) versus

**FIGURE 1.** Case Distribution (%) of Leading Cancer Types in Adolescents and Young Adults, 2012 to 2016. Coding for cancers of the thyroid, female breast, colon and rectum, and uterine cervix and melanoma of the skin are based on the Surveillance, Epidemiology, and End Results adult recode variable, excluding a small number of sarcomas of the bone and soft tissue. HL indicates Hodgkin lymphoma; NHL, non-Hodgkin lymphoma; ONS, other nervous system.

adult cancers (eg, thyroid cancer and melanoma of the skin) compared with those aged 20 to 39 years. The most commonly diagnosed cancers are thyroid cancer, Hodgkin lymphoma, and brain and other nervous system cancers among adolescents; thyroid cancer, testicular germ cell tumors (GCTs), and melanoma of the skin in the group aged 20 to 29 years and female breast cancer, thyroid cancer, and melanoma in those aged 30 to 39 years (Table 2). Notably, the only commonality among the top 3 sites in each age group is thyroid cancer.

### Incidence

Among AYAs, incidence increases with advancing age for all cancer types except for ALL, bone tumors, and Hodgkin

lymphoma, for which rates are highest in adolescents (Table 3). Cancer incidence rates for all sites combined are similar by sex in AYAs aged 15 to 19 years (23 vs 24 cases per 100,000 population in females and males, respectively, during 2012–2016). Rates in women compared with men, however, are 30% higher in AYAs aged 20 to 29 years (55 vs 42 per 100,000 population) and nearly double in those aged 30 to 39 years (161 vs 84 per 100,000 population) (Table 3),<sup>19</sup> primarily because of the substantially higher incidence of breast and thyroid cancers and melanoma of the skin in women. For example, thyroid cancer incidence rates among women in their 20s are greater than 5-fold higher than those among men (15 vs 3 per 100,000 population during 2012–2016, respectively).<sup>19</sup> Notably, although lung cancer is rare in AYAs, rates among women in their 30s are higher than those among men despite lower smoking prevalence in women; research is ongoing to elucidate the causes of this pattern.<sup>26</sup>

Long-term trends in cancer incidence rates among AYAs by age group are shown in Figure 2. Rates among men aged 20 to 39 years rapidly increased in the late 1980s and subsequently declined in the early 1990s in parallel with the human immunodeficiency virus (HIV)/acquired immune deficiency syndrome (AIDS) epidemic, primarily reflecting a peak in the occurrence of Kaposi sarcoma (Fig. 3). During the past decade of available data (2007–2016), overall incidence rates increased in all AYAs, but may be stabilizing among men in their 20s (Fig. 2). Rising rates in AYAs, especially among women, are largely driven by the increased detection of thyroid cancer, for which rates rose by almost 3% annually among adults aged 20 to 39 years and 4% annually among adolescents during 2007 through 2016 (Table 4).<sup>13</sup> Indeed, when thyroid cancer is excluded from overall trends, rates in women during 2007 through 2016 were stable. Increases in thyroid cancer incidence

**TABLE 2.** Leading Sites of New Cancer Cases in Adolescents and Young Adults, Both Sexes Combined: 2020 Estimates<sup>a</sup>

AGES 15 TO 19 YEARS		AGES 20 TO 29 YEARS		AGES 30 TO 39 YEARS

Abbreviation: ONS, other nervous system.

<sup>a</sup>Incidence and death rates are per 100,000 population and are age adjusted to the 2000 US standard population. Mortality and incidence are not directly comparable for some cancer types for which cases are defined using histology information, including testicular germ cell tumors, brain and ONS tumors, bone tumors, and soft-tissue sarcomas.

<sup>b</sup>These exclude benign and borderline brain tumors.

<sup>c</sup>For incidence and survival, coding for these cancer types correspond to the following adolescent and young adult site recode/World Health Organization 2008 definitions: bone tumors, including osseous and chondromatous tumors, brain and ONS tumors, central nervous system tumors, and other intracranial and intraspinal tumors.

<sup>d</sup>Data are not shown because there were fewer than 16 cases or deaths or could not be calculated because of data limitations.

Source: Incidence, North American Association of Central Cancer Registries, 2019; mortality, National Center for Health Statistics, 2019; survival, Surveillance, Epidemiology, and End Results (SEER 18) registries, 2019.

**FIGURE 2.** Trends in Adolescent and Young Adult Cancer Incidence and Mortality Rates for All Cancers Combined by Age and Sex, 1975 to 2017. Rates are age adjusted to the 2000 US standard population, and incidence rates are adjusted for reporting delays. Rates for those aged 15 to 19 years are 2-year moving averages.

rates have occurred across all age groups (Fig. 4), largely reflecting increased detection because of advances in imaging.<sup>27</sup> Other cancers for which rates are increasing in AYAs include those that have similarly been linked to increased detection (eg, kidney), as well as those cancers associated with the obesity epidemic (eg, colorectal, kidney, uterine corpus, and possibly leukemia).<sup>28,29</sup> However, the extent to which known risk factors contribute specifically to the rising incidence in AYAs is unclear, and further research is needed. For example, the increase in kidney cancer, which is the most rapidly increasing cancer across all AYA age groups, is largest for high-grade, aggressive tumors and renal cell carcinoma; renal pelvic cancer rates have not similarly increased, as would be expected from increased detection.<sup>30</sup>

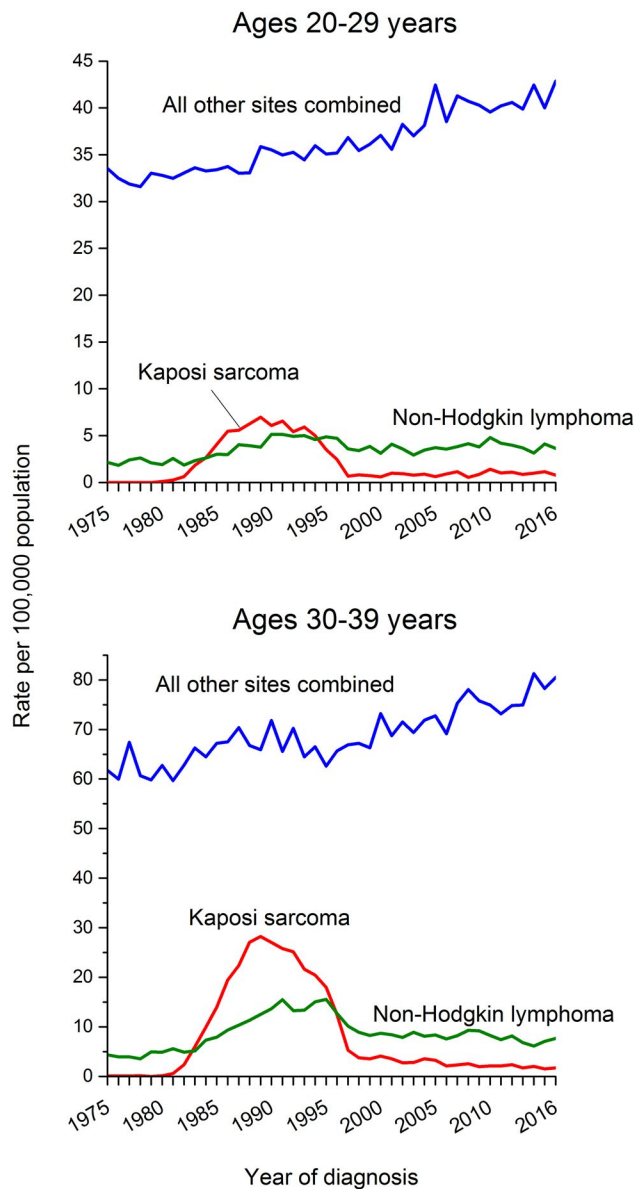

By race/ethnicity, cancer incidence rates among AYAs are highest in non-Hispanic Whites (83 per 100,000 population) and lowest in Asian/Pacific Islanders (APIs) (54 per 100,000 population) for both sexes (Fig. 5). This reflects generally higher rates in non-Hispanic Whites for thyroid cancer, testicular GCTs, and melanoma compared with other major racial/ethnic groups. Overall incidence rates during 2007 through 2016 increased among AYA women for all racial/ethnic groups except AI/ANs (Table 5), among whom rates were stable. Incidence was generally stable among men across all racial/ethnic groups except for APIs and Hispanics, among whom rates increased annually by 1.5% and 0.8%, respectively. These increases largely reflect rates for testicular GCT and thyroid cancer, especially among Hispanics, among whom testicular GCT incidence rates rose by nearly 3% annually, for reasons that are unknown.<sup>15</sup>

### Cancer Survival and Stage Distribution

Except for a decline during the HIV/AIDS epidemic from the mid-1980s to the mid-1990s among men aged 20 to 39 years, overall 5-year survival among AYAs has increased since the mid-1970s.<sup>12,13</sup> Five-year relative survival rates for AYA patients diagnosed during 2009 through 2015 were generally similar across age groups (range, 83%–86%) (Table 3) and were comparable to the rate in children (84%) but were substantially higher than that in adults aged  $\geq 40$  years (66%).<sup>13</sup> However, overall AYA cancer survival is largely influenced by the high survival rates of thyroid cancer,<sup>31</sup> which has a 5-year survival rate  $>99\%$ . In addition, many other common cancers in young adults have high 5-year survival rates (eg,  $\geq 94\%$  for testicular GCTs, melanoma, and Hodgkin lymphoma) because of highly effective treatment for testicular GCTs, Hodgkin lymphoma, and early-stage melanoma (Table 3). AYAs are diagnosed at earlier stages than older adults for most cancers except colorectal and female breast cancers, which is due not only to screening differences but also to diagnosis delays resulting from less access to health care.<sup>32</sup>

Despite comparable cancer survival in AYAs and children, survival in AYAs is lower for some cancer types.<sup>33,34</sup> For example, the 5-year relative survival rate for patients with ALL who were diagnosed during 2009 through 2015 was higher in children (91%) than in AYAs overall (60%) and in every age group (Table 3).<sup>13</sup> Similarly, the 5-year survival rate for patients with non-Kaposi soft-tissue sarcoma was lower in AYAs than in children (73% vs 81%) despite higher survival during 1975 through 1977 (70% vs 58%).<sup>12</sup>

Five-year cancer-specific survival in AYAs for all cancer types combined is lower in racial/ethnic minorities, especially

**FIGURE 3.** Kaposi Sarcoma and Non-Hodgkin Lymphoma Incidence Rates Compared With All Other Cancers Combined Among Young Adult Men, 1975 to 2016. Incidence rates are age adjusted to the 2000 US standard population and are adjusted for reporting delays.

individuals who are non-Hispanic Black (75%) compared with those who are non-Hispanic White (88%) (Fig. 6).<sup>13</sup> Some of the largest disparities occur among those who are non-Hispanic Black and Hispanic compared with non-Hispanic Whites for ALL (57% and 58% vs 71%, respectively) and female breast cancer (78% and 85% vs 89%, respectively) and among AI/ANs compared with non-Hispanic Whites for colorectal cancer (59% vs 72%, respectively). These disparities are not only driven by differences in the timeliness and quality of diagnosis and treatment as a result of inequities in insurance status and access to care but also by differences in tumor characteristics, such as estrogen receptor status for female breast cancer.<sup>10,35</sup>

### Mortality

The leading causes of cancer death differ substantially by age group (Table 6). In 2017, leukemia and brain tumors were among the leading cancer causes of death in all sex and age groups except women aged 30 to 39 years, among whom breast, cervical, and colorectal cancers were the leading cancer causes of death. Importantly, leukemia continues to be the leading cause of cancer death in both adolescents and adults aged 20 to 29 years, a point that is masked when adolescents are combined with children, among whom brain cancer is the leading cancer cause of death.<sup>36</sup>

In contrast to incidence, cancer death rates among AYAs aged 15 to 29 years are higher in males than in females (Table 3) because of differences in case distribution and lower survival in males for some common cancers (eg, melanoma).<sup>16</sup> By race/ethnicity, non-Hispanic Black AYAs have the highest cancer mortality rates (11 per 100,000 population) despite 25% lower incidence rates than those in non-Hispanic Whites. In women, this largely reflects substantial disparities in breast cancer mortality; breast cancer death rates in non-Hispanic Black women in their 30s are nearly double those in non-Hispanic White women (8.5 vs 4.5 deaths per 100,000 population, respectively).<sup>17</sup>

Cancer mortality rates in AYAs have been steadily declining in all age and sex groups since at least 1975 (Fig. 2). Notably, these trends do not reflect the impact of the HIV/AIDS epidemic because deaths from HIV/AIDS-related cancers are often attributed to the underlying viral infection. In addition, Kaposi sarcoma was not a separate reportable cause of death until 1999. During the most recent 10 years of available data (2008-2017), mortality rates for all cancers combined declined on average by approximately 1% per year in both men and women but leveled off in recent years among women aged 30 to 39 years, likely reflecting stable rates for breast cancer mortality after more than 2 decades of decline (Table 4). By race/ethnicity, mortality declines over the past decade were steepest in non-Hispanic White and Black AYAs and were stable in Hispanics, AI/AN men, and API women (Table 5).

### Selected sites

#### *Brain and other nervous system tumors*

Malignant brain and other nervous system tumors (also referred to as brain cancer) are a substantial cause of morbidity and mortality in AYAs. An estimated 3700 cases of malignant brain tumors are expected to be diagnosed among AYAs in 2020 (Table 2). Brain cancer is the most common cause of cancer death in AYA men and the second leading cause overall after breast cancer (Table 6). Gliomas account for the majority of cases in AYAs, similar to other age groups. Among AYAs, however, there is substantial heterogeneity in the distribution of other brain tumor subtypes by age: adolescents have a higher

Abbreviations: AAPC, average annual percent change; ONS, other nervous system.

<sup>a</sup>Fixed-interval trends represent the 10-year AAPC based on 1995 to 2016 incidence rates and 1975 to 2017 mortality rates. AAPCs were calculated allowing up to 4 joinpoints for incidence trends and 5 joinpoints for mortality trends.

<sup>b</sup>The AAPC is statistically significantly different from zero ( $P < .05$ ).

<sup>c</sup>Data were too sparse in some data years to calculate trends.

<sup>d</sup>Cancers of the appendix were excluded from incidence trends.

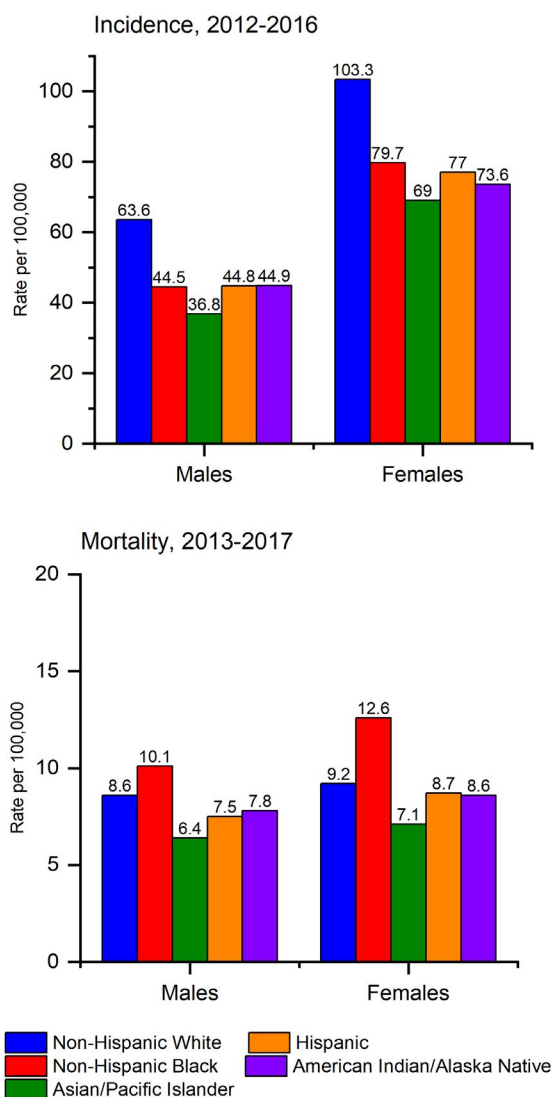

**FIGURE 4.** Trends in Adolescent and Young Adult Cancer Incidence Rates by Site and Age, 1995 to 2016. Rates are age adjusted to the 2000 US standard population and are 2-year moving averages. HL indicates Hodgkin lymphoma; NHL, non-Hodgkin lymphoma; ONS, other nervous system.

proportion of intracranial GCTs and other brain tumors associated with childhood, such as medulloblastoma, than those aged 20 to 39 years.<sup>37</sup> For example, during 2012 through 2016,

medulloblastoma accounted for 9% of brain and other nervous system tumors in adolescents compared with 3% of tumors in the group aged 30 to 39 years.

**FIGURE 5.** Cancer Incidence and Mortality Rates by Sex and Race/Ethnicity, Ages 15 to 39 Years, 2012 to 2017. Rates are per 100,000 population and age adjusted to the 2000 US standard population. Rates for American Indians/Alaska Natives are based on Preferred/Referred Delivery Care Area counties.

From 2007 to 2016, brain cancer incidence rates were stable in adolescents and declined among adults aged 20 to 39 years (Table 4). Reasons for these trends are unknown, as there are few established risk factors for brain tumors other than exposure to ionizing radiation.<sup>38</sup> Current trends may be influenced by recent changes in reporting after an improved understanding of tumor biology, as has been hypothesized for younger age groups.<sup>39</sup> The 5-year relative survival rate for malignant brain tumors ranges from 77% in adolescents to 66% in the group aged 30 to 39 years, largely reflecting differences in the aggressiveness of glioma subtypes by age.<sup>13</sup> For example, the 5-year relative survival rate for patients with astrocytoma who were diagnosed during 2009 through 2015 was 76% in adolescents compared with 50% in the group aged 30 to 39 years.

**TABLE 5.** Ten-Year Fixed-Interval Trends in Cancer Incidence (2007-2016) and Mortality (2008-2017) Rates by Race/Ethnicity in Adolescents and Young Adults<sup>a</sup>

Abbreviation: AAPC, average annual percent change.

<sup>a</sup>Fixed-interval trends represent the 10-year AAPC based on 1995 to 2016 incidence rates and 1990 to 2017 mortality rates. AAPCs were calculated allowing up to 4 joinpoints for incidence trends and 5 joinpoints for mortality trends.

<sup>b</sup>The AAPC is statistically significantly different from zero ( $P < 0.05$ ).

Benign and borderline brain tumors account for a large proportion of overall cases of brain tumors in all age groups; among AYAs in particular, this percentage ranges from 48% in adolescents to 63% in the group aged 30 to 39 years.<sup>14</sup> Incidence rates for these cancers, which were not reportable until 2004, have increased in recent years largely because of improvements in reporting.<sup>40</sup> The overall 5-year relative survival rate for benign and borderline tumors is relatively high, at approximately 97%, in all AYA age groups.<sup>41</sup>

#### Female breast

Breast cancer is the most commonly diagnosed cancer among women aged 30 to 39 years, with an estimated 11,100 cases expected in 2020 (Table 2). It is the leading cancer cause of death in AYA women, accounting for 22% of cancer deaths in 2017 (Table 6). The risk of developing breast cancer at a young age is higher for women with a family history of the disease, particularly a diagnosis in a relative aged younger than 50 years and in those with heritable mutations in cancer susceptibility genes (eg, *BRCA1/BRCA2*) or certain other genetic syndromes (eg, Li-Fraumeni syndrome).<sup>42</sup> However, most AYA women who are diagnosed with breast cancer do not have these risk factors.<sup>43</sup> Reproductive risk factors generally do not appear to differ long-term by age or menopausal status.<sup>44,45</sup> However, among younger women, the risk of breast cancer is temporarily increased after first birth.

Incidence rates in non-Hispanic Black AYAs are 14% higher than those in non-Hispanic White AYAs (25.9 vs 22.3 per 100,000 population during 2012-2016)<sup>19</sup> in contrast to older women, among whom rates are highest in Whites. However, higher incidence rates in non-Hispanic Black AYAs are confined to hormone receptor–negative disease; in particular, triple-negative rates are >50% higher than those in non-Hispanic Whites (6.1 vs 3.9 per 100,000 population during 2012-2016, respectively).<sup>19</sup> Notably, the

**FIGURE 6.** Five-Year Cause-Specific Survival by Race/Ethnicity for Selected Cancers in Adolescents and Young Adults, 2009 to 2015. Patients were diagnosed from 2009 to 2015 and followed through 2016. \*Data are suppressed for American Indians/Alaska Natives because of sparse case numbers (<25 cases). ONS indicates other nervous system.

Abbreviation: ONS, other nervous system.

Black-White disparity in breast cancer mortality is largest in AYAs and declines with age.<sup>46</sup> Death rates in non-Hispanic Black AYAs compared with those who are White are nearly double (3.9 vs 2.0 per 100,000 population, respectively, during 2013-2017),<sup>17</sup> reflecting in part the higher rates of aggressive tumors with a poorer prognosis combined with inequities in access to high-quality cancer care.

During the most recent 10 years of available data, breast cancer incidence rates increased by nearly 2% annually among women aged 20 to 29 years and by 0.2%

annually among women in their 30s; rates in adolescents were stable. The overall increase in female breast cancer is largely driven by non-Hispanic Whites, among whom rates have increased since at least 1995.<sup>15</sup> Factors thought to be driving the increase include changes in reproductive patterns, such as declines in the fertility rate and older age at first birth. Breast cancer mortality rates are no longer decreasing in AYA women after more than 2 decades of continuous decline, likely reflecting increased incidence (Table 4) (Fig. 7).

**FIGURE 7.** Trends in Adolescent and Young Adult Cancer Mortality Rates by Site, Ages 15 to 39 Years, 1975 to 2017. Rates are age adjusted to the 2000 US standard population and are 2-year moving averages. \*These include all tumors of the testis and is not limited to germ cell tumors, because histologic information is unavailable on death certificates. HL indicates Hodgkin lymphoma; NHL, non-Hodgkin lymphoma; ONS, other nervous system.

AYA patients with breast cancer are more commonly diagnosed at an advanced stage than older patients; less than one-half (47%) are diagnosed at a localized stage compared with 60% in patients aged 45 to 54 years and 65% in those aged 55 to 64 years.<sup>19</sup> In addition to mammographic screening not being recommended for AYAs at average breast cancer risk, this also reflects diagnostic delays and a higher proportion of aggressive disease (eg, triple-negative breast cancer) at younger ages.<sup>16,47</sup> As a result, the 5-year relative survival rate for female breast cancer is lower in AYAs than in older, screening-aged women (86% vs 91% in women aged 45-64 years).<sup>19</sup>

### Colon and rectum (colorectum)

Colorectal cancer is the fourth most commonly diagnosed cancer among adults aged 30 to 39 years, with 4100 cases expected in 2020 (Table 2). In 2017, it was the leading cancer cause of death among men in this age group and the third among women (Table 6). Increasing evidence suggests that colorectal cancer in adults aged <30 years is unique from that diagnosed in older adults, in part because of a higher frequency of tumors occurring in the distal colon or rectum and exhibiting microsatellite instability and mucinous and signet ring cell histologies.<sup>48</sup> A family history of young-onset diagnosis and certain hereditary conditions (eg, Lynch syndrome, familial adenomatous polyposis) are associated with a higher risk of colorectal cancer before age 40 years.<sup>49,50</sup>

During 2007 through 2016, colorectal cancer incidence rates increased by 0.9% and 1.5% annually among the groups aged 20 to 29 years and 30 to 39 years, respectively (Table 4). Mirroring incidence, colorectal cancer mortality rates likewise increased by approximately 1% annually among those aged 30 to 39 years during 2008 through 2017. These patterns reflect a birth cohort effect in which colorectal cancer risk has been increasing in subsequent generations since 1950.<sup>51</sup> In contrast, rates in adults aged  $\geq 65$  years are continuing to rapidly decline, largely reflecting the widespread uptake of screening with colonoscopy since 2000.<sup>52</sup> Reasons for the increases in young adults are not clear but may be associated with obesity and changes in dietary factors.<sup>29</sup> Similar trends among young adults have been observed in many other high-income countries.<sup>53</sup>

The 5-year relative survival rate in the group aged 20 to 39 years for patients diagnosed during 2009 through 2015 was 68% (Table 3), similar to that in screening-aged adults.<sup>52</sup>

### Leukemia

ALL and acute myeloid leukemia (AML) account for the majority of leukemia cases in AYAs, with ALL comprising most cases in adolescents and AML becoming the predominant subtype among older AYAs (Table 2). Leukemia is among the most commonly diagnosed cancers in adolescents, with approximately 600 cases of ALL and AML combined expected in 2020. Overall, despite progress in optimizing cytotoxic chemotherapy regimens and, more recently, in molecularly targeted agents and immunotherapies, leukemia continues to be the leading cancer cause of death in the group aged 15 to 29 years (Table 6).<sup>54</sup>

From 2007 through 2016, incidence rates increased by 0.7% to 1.9% annually for ALL and by 0.4% to 1.2% for AML. Increases in leukemia may be linked to increased exposure to radiation (including computed tomography exposure) and chemotherapy, although it is unclear to what extent each of these factors contributes.<sup>55-57</sup> Obesity has also been

proposed as a contributing factor,<sup>29</sup> although this is based on prospective cohort studies that are largely confined to older adults.<sup>57</sup> The 5-year relative survival rate for ALL and AML is substantially higher in adolescents (74% and 66%, respectively) compared with older AYA age groups (Table 3), which may reflect inequities in access to care, differences in the receipt of adult versus pediatric treatment regimens, and more aggressive disease in older AYAs.<sup>58</sup> In one population-based study of AYA patients with ALL, higher overall survival was associated with pediatric regimens delivered in front-line pediatric oncology settings, regardless of age.<sup>58</sup>

### **Lymphoma**

Approximately 4200 cases of Hodgkin lymphoma and 4600 cases of non-Hodgkin lymphoma are expected to be diagnosed among AYAs in 2020. Whereas Hodgkin lymphoma accounts for the majority of lymphomas diagnosed in AYAs aged 15 to 29 years, non-Hodgkin lymphoma is more common in the group aged 30 to 39 years (Table 2). Non-Hodgkin lymphoma includes a constellation of subtypes that vary in occurrence by age. For example, Burkitt lymphoma accounts for a higher proportion of cases in adolescents than in older AYAs (15% vs 4% in those aged 30-39 years).<sup>14</sup> Established risk factors for both Hodgkin lymphoma and some types of non-Hodgkin lymphoma (eg, Burkitt lymphoma) include prior infection with Epstein-Barr virus (EBV) as well as immunocompromising conditions, such as infection with HIV and immunosuppression after organ transplantation.<sup>59,60</sup> Notably, although EBV-associated Hodgkin lymphoma cases appear to peak in AYAs aged 15 to 24 years, non-EBV-associated Hodgkin lymphoma is more common among older AYAs.<sup>59</sup> The risk for Hodgkin lymphoma and some non-Hodgkin lymphoma subtypes has also been linked to a family history of disease, particularly in siblings.<sup>61,62</sup> Diffuse large B-cell lymphoma may also be linked to obesity.<sup>63</sup>

Incidence rates for Hodgkin lymphoma declined by 0.2% to 1% annually across age groups from 2007 through 2016, while death rates declined even more dramatically, by 10% per year, during 2008 through 2017 (Table 4). Conversely, non-Hodgkin lymphoma incidence trends differ directionally by age, increasing by 1% annually in adolescents but declining in the group aged 30 to 39 years by 1% annually. However, overall non-Hodgkin lymphoma death rates are declining across AYA age groups. The 5-year relative survival rates for Hodgkin lymphoma and non-Hodgkin lymphoma exceeds 94% and 83%, respectively, across all AYA age groups but are slightly higher for adolescents than for older AYAs (Table 3).

### **Melanoma of the skin**

Melanoma is the third most commonly diagnosed cancer in the group aged 20 to 39 years. An estimated 7900

cases are expected in 2020 among all AYAs combined. It is substantially more common in AYA women than in AYA men, in contrast to older adults, among whom rates are higher in men. Spitzoid malignant melanomas, some of which can be difficult to distinguish from benign Spitz nevi because of similarities in some clinical and histologic features, are rare but account for a higher proportion of melanoma cases in younger individuals compared with older adults.<sup>64</sup> In general, melanoma of the skin in AYAs appears to occur among susceptible individuals through genetic interactions with ultraviolet light exposure in early life, whereas melanoma in older adults likely reflects cumulative lifetime ultraviolet light exposure among those with comparatively less susceptibility.<sup>65</sup> Although indoor tanning has decreased in the United States,<sup>66</sup> its prevalence in young adult women remains substantially higher than that in older women and in men overall.<sup>18</sup> Indoor tanning use is particularly important for AYAs, as the risk of melanoma is approximately 60% higher for people who begin use before age 35 years, and the risk increases with duration and intensity of use.<sup>67,68</sup>

Melanoma incidence rates have rapidly declined in adolescents (6.2% annually during 2007-2016) and adults in their 20s (3.5% annually) after peaking in the early to middle 2000s (Table 4). Among the group aged 30 to 39 years, melanoma rates were stable among women in the most recent time period but slightly declined among men. Recent declines in younger AYAs may reflect successful interventions to reduce indoor tanning and increase sun-protective behaviors.<sup>66</sup> Mirroring incidence, mortality in AYAs has rapidly declined by approximately 5% annually. The 5-year relative survival rate is generally high for melanoma in AYAs (ie, >94%), reflecting the high proportion of cases (80%) diagnosed at an early stage (Fig. 8). Although the higher proportion of spitzoid melanoma cases in younger patients has been proposed to confer a survival advantage compared with older patients, existing research has largely focused on pediatric cases, and further research specific to AYAs is needed.<sup>64</sup>

### **Testicular germ cell tumors**

Gonadal GCT rates are substantially higher in AYA men than in AYA women for reasons that are largely unknown but may reflect sex-specific interactions between genetic factors and maternal hormones before birth.<sup>17</sup> An estimated 6500 cases of testicular GCT are expected to be diagnosed in AYA men in 2020 (Table 2). Testicular GCTs are the most commonly diagnosed cancer among men aged 20 to 39 years, with rates peaking at ages 30 to 39 years (13 per 100,000 population during 2012-2016).<sup>19</sup> Testicular GCT rates are highest in non-Hispanic Whites (13 per 100,000 population), followed by Hispanics (10 per 100,000 population), and AI/ANs (10 per 100,000 population), and are lowest in non-Hispanic Black AYAs (2.4 per 100,000 population).<sup>19</sup> With the exception of cryptorchidism and Klinefelter syndrome, risk factors

**FIGURE 8.** Stage Distribution for Selected Cancers in Adolescents and Young Adults, 2012 to 2016.

for testicular GCT are not well described, although a family history of testicular GCT in a first-degree relative has been shown to increase risk 4-fold.<sup>12,18</sup>

During the most recent 10 years of available data, incidence rates for testicular GCTs increased in all AYA age groups by 0.4% to 1.1% annually, whereas mortality rates were stable (Table 4). Little is known about the causes of the rising incidence rates of testicular GCTs, but trends may reflect changes in *in utero* exposures to maternal hormones as well as other environmental exposures.<sup>69,70</sup> A strong birth cohort effect in testicular GCTs has been described in the United States and several northern European countries, where rates are likewise increasing.<sup>53</sup> The 5-year relative survival rate is generally high for testicular GCTs, exceeding 95% in all age groups (Table 3)

### Thyroid

Thyroid cancer is the most commonly diagnosed cancer in adolescents and in AYAs aged 20 to 29 years in both sexes combined. An expected 14,400 cases are projected to be diagnosed in 2020 among all AYAs (Table 2); most of these cases will occur among women. Similar to older adults, papillary thyroid cancer accounts for most cases of thyroid cancer in AYAs. During the most recent 10 years of available data, thyroid cancer incidence rates rose rapidly in all AYA age groups, whereas mortality rates declined slightly by 0.5% annually (Table 4). Although much of the increase in incidence rates has been attributed to increased detection, it is increasingly recognized that there may be a true rise in the burden of advanced-stage papillary thyroid cancer;<sup>27</sup> however, data for AYAs are sparse. In one study, exposure to tomographic scans substantially increased the risk of subsequent thyroid cancer by greater than 2-fold.<sup>55</sup> The 5-year relative survival rate for thyroid cancer is generally high and exceeds 99% in AYAs aged 20 to 39 years (Table 3). Previous studies have found that, although AYAs are more likely to be diagnosed with larger thyroid cancers or with locoregional lymph node involvement compared with

older patients, they are less likely to be diagnosed with distant metastases and continue to have a better prognosis than their older counterparts.<sup>71</sup>

### Uterine cervix

In 2020, an estimated 3800 cases of cervical cancer are expected among women aged 20 to 39 years (Table 2). Cervical cancer is the second leading cancer cause of death among women aged 30 to 39 years and among AYA women overall. All cases of cervical cancer are attributable to persistent infection with human papillomavirus, although susceptibility may be increased by cigarette smoking and immunocompromising factors.<sup>72</sup> Recent use of oral contraceptives has also been shown to slightly increase risk.<sup>73</sup> However, the cancer can be prevented through vaccination against HPV infection or removal of precancerous lesions detected via screening. From 2013 through 2018, the percentage of women aged 18 to 26 years who reported ever initiating human papillomavirus vaccination ( $\geq 1$  dose) increased from 37% to 54%, while series completion ( $\geq 2$  doses) increased from 26% to 35%.<sup>74</sup> Squamous cell carcinoma is the most common histologic type for all age groups, although childhood cancers that are not detectable through routine screening, such as embryonal rhabdomyosarcoma, occur among young AYAs.<sup>75</sup>

Cervical cancer incidence rates decreased by 1.6% annually during 2007 through 2016 among women in their 20s but appear to have stabilized among women in their 30s. The stable trend in women aged 30 to 39 years in part reflects attenuating declines in squamous cell cervical cancer rates combined with slight increases in adenocarcinoma rates.<sup>76,77</sup> The 5-year relative survival rate for patients diagnosed during 2009 through 2015 was 82% for patients aged 20 to 29 years and 80% for those aged 30 to 39 years (Table 3). Nearly one-third of cases (34%) are diagnosed at the regional or distant stage, which may reflect screening delays or more aggressive histologic subtypes, particularly in younger AYA women. In 2018, approximately 74% of AYAs aged 21 to 29 years were up to date with cervical

cancer screening, compared with 90% of adults aged 30 to 39 years and 86% of adults aged 40 to 65 years.<sup>18</sup>

## Survivorship

AYA cancer survivors are at risk of several late and long-term effects that can influence cognitive, psychosocial, and physical functioning as well as financial prospects.<sup>78,79</sup> Although cancer treatment regimens in AYAs can be tailored to minimize long-term and late effects, there is a paucity of data from clinical trials to support modifications.<sup>80</sup> In addition, similar to childhood cancer survivors, AYA cancer survivors have a notably higher risk of developing subsequent cancers compared to the general population. In one population-based study, approximately 14% of AYA cancer survivors developed a subsequent cancer 30 years postdiagnosis, with melanoma and breast, gastrointestinal, and genitourinary cancers being the most common subsequent malignancies.<sup>6</sup> Another recent analysis of population-based data found that, whereas all-cause late mortality among 5-year AYA cancer survivors declined from 8% among those diagnosed during 1975 through 1984 to 5% among those diagnosed during 2005 through 2011, little improvement in late mortality from the original cancer was observed for several cancer types, including colorectal cancer, bone and soft-tissue sarcomas, and cervical cancer.<sup>81</sup>

Although much regarding AYA cancer survivorship continues to be extrapolated from childhood cancer survivor cohorts,<sup>80</sup> recent studies have pointed to notable differences between these 2 patient groups, highlighting the need for survivorship studies specific to AYAs. For example, in a retrospective cohort study of childhood and adolescent survivors, patients diagnosed at ages 15 to 20 years had lower long-term risks of severe, chronic health problems than childhood cancer survivors but a 1.5-fold higher risk of dying from recurrence or progression of their primary cancer.<sup>9</sup> Furthermore, compared with both younger and older patient populations and cancer-free peers, AYA cancer survivors report worse overall psychosocial functioning, which may reflect difficulty in coping with cancer during early life transitions.<sup>82-84</sup>

Cancer and its treatment can cause substantial disruptions in school and career, as well as changes in functioning and appearance, leading to further challenges in resuming daily-life activities.<sup>85</sup> Difficulties with fertility, sexual dysfunction, and body image, particularly among women, are common among AYA cancer survivors.<sup>8,86</sup> Among AYA survivors who need specific services, a high proportion report a variety of unmet

needs within a year after diagnosis, such as access to a mental health professional (56%), cancer rehabilitation (58%), or pain-management services (63%).<sup>87</sup> Notably, a substantial proportion of AYA patients with cancer, especially women, do not receive adequate information about fertility preservation. In one study of AYA cancer survivors, 18% of males and 38% of females had not made such fertility-preservation arrangements because they were not aware of these options.<sup>88</sup>

Finally, AYA cancer survivors experience more financial hardship than the general population and spend more on out-of-pocket medical costs,<sup>89</sup> which is compounded by higher uninsured rates among AYAs compared with other age groups. In 2018, uninsured rates in AYAs aged 19 to 25 years were similar to those in the group aged 26 to 34 years (14%), compared with 12% among those aged 34 to 44 years and 9% among those aged 45 to 64 years.<sup>90</sup> Being uninsured or having public health insurance is associated with significant delays in diagnosis in AYAs, leading to poorer outcomes and more extensive treatment.<sup>91</sup> Compared with older survivors, young survivors have higher rates of bankruptcy and more frequently forgo needed medical care because of cost.<sup>92</sup>

## Conclusions

Although there has been rapid progress in the scientific understanding of cancer in AYAs over the last decade, several research gaps in etiology, basic biology, treatment, and survivorship remain. AYAs diagnosed with cancer also continue to face numerous challenges in health care access during early life transitions, which can negatively impact the timeliness of and adherence to treatment. Although declining mortality rates for hematologic malignancies in AYAs point toward progress in effective treatment for these cancers in recent decades, this progress has lagged behind that for children for some cancers, especially in older AYAs. Further progress in reducing cancer morbidity and mortality among AYAs could be addressed through more equitable access to health care; increasing clinical trial enrollment; expanding research on etiology, basic biology, and survivorship; and greater alertness among clinicians and patients for early symptoms and signs of cancer. Research on cancer in AYAs should also consider the heterogeneity in cancer occurrence within this patient population. In addition, further monitoring of population-based trends for cancers for which mortality rates are increasing, including colorectal and uterine corpus cancers, is warranted. ■
